Chapter 1 Outline

This chapter outlines the MX887015A CDMA Reverse Link Transmission Measurement software option. Refer to Appendix A “Specifications” for the software functions and performance.

1.1 Outline

The MX887015A CDMA2000 Reverse Link Transmission Measurement software (hereafter MX887015A) adds the 3GPP2-specified CDMA2000 1xRTT measurement function to the MU887000A TRX Test Module.

Forward Link RF signals are output from the MU887000A to the RF connector of the mobile station, and Reverse Link signals are output from the mobile station to the MU887000A.

Note:

The Signalling method, which detects Reverse Link signal information, such as call processing with the mobile station, and changes the Forward Link signal modulation, is not supported.

Reverse Link signals analyzed by the MX887015A are limited to patterns set to Long Code Mask = 0x00x00000000000.

The MX887015A supports setting of an arbitrary waveform file pattern for sending as the Forward Link signal. Regardless of the Reverse Link signal information, the modulated waveform pattern loaded from memory is sent as the Forward Link signal (Non-signalling method).

When performing the RX measurement by the MX887015A, execute the FER measurement by the mobile station.

1.2 Features

The MX887015A software features:

(1) High-speed Measurement

The up-to-date processor and measurement algorithm support high-speed measurement.

(2) Sequence Measurement

Multiple measurements can be performed sequentially using preprogrammed measurement conditions. The Sequence Measurement mode helps cut mobile station test times.

1.3 Composition

The composition of MX887015A is shown in Table 1.3-1.

Table 1.3-1 Composition

Item	Model/Code	Name	Qty	Remarks
Software		Storage media (DVD, etc.)	1

	W3611AE	MX887015A CDMA2000 Reverse Link TX Measurement Operation Manual		English, on storage media (DVD, etc.)

1.4 License Registration

Before the MX887015A software can be used, the software license must be registered in the MU887000A.

Refer to Chapter 8 “Utility Tool” in *the MU887000A TRX Test Module Operation Manual* for the license registration procedure.

Chapter 2 Fundamental Measurement

This chapter describes the fundamental functions and commands of the MX887015A. For details of the commands, refer to Chapter 4 “SCPI Command Reference” and Chapter 5 “Native Command Reference”.

2.1 Common Operations

This section explains operations that are common to the measurements in Chapter 3 "Sequence Measurement".
Both Native and SCPI commands are described in the introduction to commands.

2.1.1 Selecting application

Switch the MU887000A application software to cellular by setting the parameter to CELLULAR using the following command.

```
SYSSEL
:INSTrument[:SELect]
```

Switch the MX887015A measurement standard using the following command. Set the parameter to CDMA2000 when a function described in section 2.2 "Transmit Power" to section 2.7 "Capturing Waveform Data" is to be used.
Set the parameter to SEQUENCE when using a function described in Chapter 3 "Sequence Measurement".

```
STDSEL
:CONFigure:CELLular:MEASurement:STANdard
```

2.1.2 Setting ports

Set the MU887000A ports to be used. The following command sets both the port for outputting the downlink signal and the port for receiving the uplink signals.
Set Port1 to Port4 at the parameter

```
PORT
:ROUTe:PORT:CONNect:DIRection
```

When setting the sequence table in sequence measurement, the sequence commands set only the output port to Port 1 to Port 4.
The above-mentioned command sets the receiving port.

2.1.3 Frequency and level

Frequency

If the Reverse Link signal does not synchronize with the Forward Link signal within the time span, enable Long Span Code Search.

Spurious Emission Limit Range

Set the band class to determine the Spurious Emission Limit range.

Chapter 3 Sequence Measurement

This chapter explains the MX887015A Sequence Measurement function and commands. For a detailed description of the commands, refer to Chapter 4 "SCPI Command Reference" and Chapter 5 "Native Command Reference" in this manual.

A license for the MX887010A Cellular Standards Sequence Measurement is required to execute sequence measurement.

3.1 Outline

The MX887015A CDMA2000 Reverse Link Transmission Measurement option adds the following measurements to the Sequence Measurement mode. Refer to Chapter 2 “Fundamental Measurement” for details of each measurement.

- Tx Power
- Occupied Bandwidth
- Spurious Emissions
- Modulation Analysis
  Frequency Error, Rho, EVM, Origin Offset, Time Error
- Code Domain Power

The Sequence Measurement mode does not support the Waveform Data measurement.

CDMA2000 measurement can be allocated to any segment in the sequence table.
The segment duration depends on the measurement count. Each item of CDMA2000 measurement takes 0.667 ms (≈10/15 ms).
When multiple measurements are specified in a segment, the largest measurement count determines the segment measurement duration.

Example:

Tx Power	50 times	50 × 10/15 ms = 33.3 ms
Occupied Bandwidth	100 times	100 × 10/15 ms = 66.7 ms
Spurious Emissions	150 times	150 × 10/15 ms = 100 ms
Modulation Analysis	50 times	50 × 10/15 ms = 33.3 ms
Code Domain Power	200 times	200 × 10/15 ms = 133.3 ms

In this case, the measurement duration is 133.3 ms as determined by the Code Domain Power measurement duration.

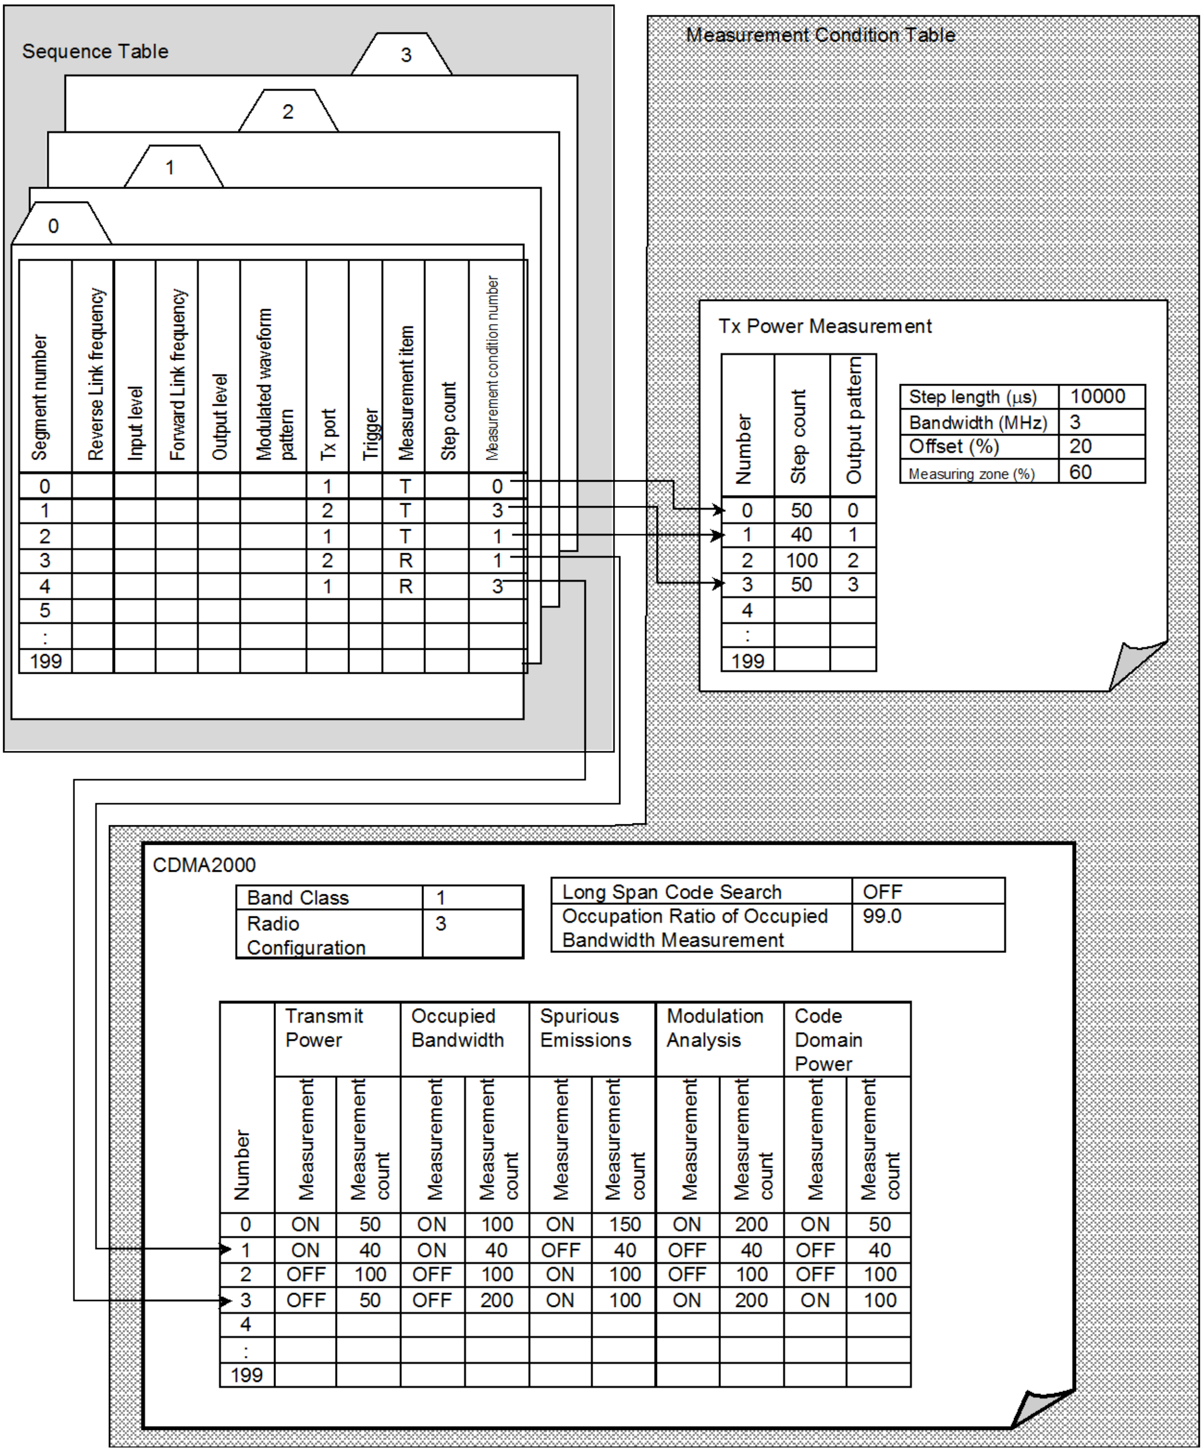

Figure 3.1-1 Data Composition of Sequence Measurement Condition with MX887015A Installed

To change measurement to the Sequence Measurement mode send the following command to set the parameter to SEQUENCE.

```
STDSEL
:CONFigure:CELLular:MEASurement:STANdard
```

To modify the frequency, level or waveform pattern of a downlink signal at sequence measurement, set the MU887000A vector signal generator to the Sequence Measurement mode. Set the parameter to SEQUENCE using the following command. For detailed descriptions of commands, refer to Chapter 5 “SCPI Command Reference” in the *MU887000A TRX Test Module Operation Manual*.

```
:SOURce:GPRF:GENerator:MODE
```

Set the initial sequence measurement conditions to the following items described in Section 2.1 “Common Operations”.
Individual values can be set for each of the following items described in Chapter 2 “Fundamental Measurement” and in this chapter.

3.2 Sequence Table Setup

3.2.1 Sequence table setting items

The sequence table setting items are:

- Table number
- Reverse Link frequency
- Input level
- Forward Link frequency
- Output level
- Modulated waveform pattern
- Output port
- Trigger conditions
- Measurement item
- Step count
- Measurement condition number

Table Number

This is the number allocated to the edited sequence table. Four sequence tables are used and each table has a number between 0 and 3.

Reverse Link frequency, Input level, Forward Link frequency, Output level, and Modulated waveform pattern

Each segment of the sequence table is configured with frequencies (MHz) and levels (dBm) and modulated waveform pattern number. The setting ranges are:

Frequency:	400.000000 to 3800.000000 MHz
Input Level:	–65.0 to +35.0 dBm (Test Port 1, 2)
	–65.0 to +25.0 dBm (Test Port 3, 4)
Output Level:	–130.0 to–10.0 dBm (Test Port 1, 2)
	–120.0 to 0.0 dBm (Test Port 3, 4)
Modulated Waveform Pattern:	PAT1 to PATn (n: waveform information file group range)

For details of the modulated waveform patterns at CDMA2000 measurement, refer to Section 2.1.5 Waveform patterns.

Output port

This sets the number of the RF signal output port to 1 to 4 in each segment of the sequence table.
When selecting Port 3 or 4, make sure the port number is not the same as the input port.

Trigger condition

This specifies the trigger condition at each segment of the sequence table.
The setting ranges are:

Trigger Source:	Frame: When frame is detected Free run: When measurement start command received Power: When input level above (below) trigger level
Slope:	Rise: When input level exceeds trigger level
Trigger Level:	Level difference from input level Set a value in the range of –40.0 to 0 dB.
Trigger Delay:	Delay time Set a value in the range of 0 to 10.000 ms.

Measurement item, Step count and Measurement condition

This sets the step count and measurement item for received signals in each segment of the sequence table. To execute the CDMA2000 measurement described here, set CDMA2000 as the measurement mode.

Note:

If the license of other cellular application software is installed, the measurement mode supported by the license can be set.

In this case, the measurement mode can be changed up to 15 times during the sequence.

The CDMA2000 measurement condition is specified in a separate table. A measurement item should be registered in a given segment with its measurement condition number specified in the related table.
Set the step count to the following values or more according to the contents of the CDMA2000 measurement condition table.

- Measurement Count + 2
- Step number of trigger segment* is 16 or above.
  *: A start segment of sequence measurement or a segment whose trigger source is not set to Freerun.

Step count setting examples are shown in the following table.

Table 3.2.1-1 Example of Step Count Settings

	Measurement	Example 1		Example 2	
		Measurement	Measurement count	Measurement	Measurement count
*1	Tx Power	On	50	On	50
	Occupied Bandwidth	On	100	On	100
	Spurious Emissions	On	60	On	60
	Modulation Analysis	On	200	On	200
	Code Domain Power	On	100	Off	100
*2	Step Count		202		202

*1: Setup items specified in CDMA2000 measurement condition table

*2: Setup items specified in sequence table

3.2.2 Sequence table commands

The following commands set and query items in the sequence table.

- Table Number
  `SEQTBL`
  `:CONFigure:CELLular:SEQuence:TABLe`
- Reverse Link Frequency, Input Level, Forward Link Frequency, Output Level, and Modulation Pattern
  `SEQTRX`
  `:CONFigure:CELLular:SEQuence:RFSettings:TRX`
- Reverse Link Frequency and Input Level

3.2.3 Setting item error check

Setting errors in the following items in the sequence table can be checked.

- Input level
- Output level
- Step count
- Waveform pattern
- Port
- Amount of capture memory
- Output level change count
- Waveform pattern change count
- Measurement mode change count

The following command is used to check for errors.

```
SEQERR
:FETCh:CELLular:SEQuence:ERRor
SEQERR2
:FETCh:CELLular:SEQuence:ERRor2
```

Capture memory is used to save the CDMA2000 measurement results. One CDMA measurement uses about 0.013% of the memory, so 1.3% of the capture memory is required to execute 100 measurements for a specific segment.
The following table shows error causes.

Table 3.2.3-1 Error Cause

Parameter	Cause
Input level*	Input level is out of range.
Output level*	Output level is out of range.
Step count	Fail to satisfy the step count conditions in Section 3.2.1.
Waveform pattern	The specified waveform file is not loaded in the waveform memory. The specified waveform pattern does not exist in the waveform file.
Port	Port 3 is set for both input port and output port. Or Port 4 is set for both input port and output port.
Amount of capture memory	Memory use rate is 100% or above
Output level change count	Output level change count is 3001 or above.
Waveform pattern change count	Waveform pattern change count is 101 or above.
Measurement mode change count	Measurement mode change count is 16 or above.

*: The available level depends on the settings of port number and external loss.

Changing the waveform pattern to CW or NC is not counted as waveform pattern change. Some examples of how to count waveform pattern change are shown below.

Parameter Setting Command	Waveform Pattern Change Count
`SEQTRX 0,1950.00,-10.00,869.20,-60.00,PAT1`	1
`SEQTRX 1,1950.00,-10.00,869.20,-60.00,CW`	1

`SEQTRX 3,1950.00,-10.00,869.20,-60.00,NC`	2
`SEQTRX 4,1950.00,-10.00,869.20,-60.00,PAT3`	3
`SEQTRX 5,1950.00,-10.00,869.20,-60.00,PAT1`	4

Details

The setting range varies with the input/output port setting.

If Cable Loss Correction is ON, the cable loss is added to the range of the input level and subtracted from the range of output level.

If the cable loss is 5 dB, the input and output levels are as follows:

Input level	–60.0 to +40 dBm
Output level	–135.0 to –15.0 dBm

In this case, if the output level is set to –10.0 dBm, an out-of-parameter setting range error occurs. (The response to :SYSTem:ERRor? returns 220, Parameter error).

Whether an out-of-parameter setting range error has occurred is determined during execution of the following commands:

:CONFigure:CELLular:SEQuence:CONTrol, :INITiate:CELLular:MEASurement:SINGle, :INITiate:CELLular:SEQuence:EXECute:TX

A measurement execution error occurs at out-of-range errors.

:FETCh:CELLular:SEQuence:ERRor? is used to query the details of errors.

The pattern number is the same as the group number. Refer to Chapter 3, “Waveform File Details” in the *Waveform Files for Cellular Application Operation Manual*.

Example of Use

To set segment 0 as follows:

Uplink frequency set to 1950.0 MHz, input level to –10.0 dBm, downlink frequency to 2140.0 MHz, output level to –60.0 dBm, no modulation:

```
:CONF:CELL:SEQ:RFS:TRX 0,1950.000000,-10.0,2140.000000,-60.0,CW
:CONF:CELL:SEQ:RFS:TRX? 0
> 1950.000000,-10.0,2140.000000,-60.0,CW
```

Remarks

The group range depends on the selected waveform file.

For details of the waveform patterns, refer to Chapter 3, “Waveform File Details” in the *Waveform Files for Cellular Application Operation Manual*.

Details

The setting range varies with the input/output port setting.
If Cable Loss Correction is ON, the cable loss is added to the range of the input level and subtracted from the range of output level.
If the cable loss is 5 dB, the input and output levels are as follows:

Input level	–60.0 to +40 dBm

In this case, if the output level is set to –10.0 dBm, an out-of-parameter setting range error occurs. (The response to SYSERR? returns 220, Parameter error).
Whether an out-of-parameter setting range error has occurred is determined during execution of the following commands:
SEQCTRL, SNGLS, SEQEXECTX
A measurement execution error occurs at out-of-range errors.
SEQERR? is used to query the details of errors.

The pattern number is the same as the group number. Refer to Chapter 3, “Waveform File Details” in the *Waveform Files for Cellular Application Operation Manual*.

Example of Use

Chapter 6 Performance Test

This chapter explains how to setup the measuring instruments required for the MX887015A CDMA2000 performance tests as well as the test procedures.

6.1 Outline

The performance tests are performed to assure that the MU887000A performance does not deteriorate. Test the performance of the MU887000A at the initial acceptance inspection, at periodic inspections, and after repairs. Test important items periodically to assure the performance. This chapter explains the following test items.

- Output Rho
- Tx Power measurement accuracy (CW)
- Tx Power measurement linearity
- Frequency/Modulation measurement Carrier frequency accuracy
  Rho

We recommend testing the performance periodically once or twice a year. If the test results do not meet the specifications, contact an Anritsu Service and Sales office. Contact information can be found on the last page of the printed version of this manual, and is available in a separate file on the PDF version.

⚠ CAUTION

Warm-up the MU887000A and the required measuring instruments for at least 30 minutes (except when specified otherwise) to stabilize them. To achieve the highest accuracy, the test should be performed at room temperature using a power supply with as little voltage fluctuation as possible in an environment free from noise, vibration, dust and humidity.

   Tx Power Measurement Results: Average value
5. Set the SG output level to –10 dB and measure the Tx power, making this value D dBm.
6. Calculate the difference between REF dBm and D dBm using the following equation.

   Linearity error = D – REF – (calibration value of section 6.3.3)
7. Similarly, change the SG output level successively from –20 dB to –40 dB in –10 dB steps and measure the Tx power. Calculate the linearity as described in step 6 and check that the results meet the specifications.
8. Change the MU887000A and SG frequencies according to Table 6.3.1-1 "Measurement Point and Frequency" and repeat steps 2 to 7 over.
9. Change the SG output level and the MU887000A input level to –25 dBm and repeat steps 2 to 8 over to measure the Tx Power. (This output level reflects the calibration value for item 6.3.1.)
10. Change the Connect port setting for the connection with the MU887000A to Test Port2/3/4 successively, and repeat steps 2 to 9 over.

4. Measure the frequency error, Rho.

Carrier Frequency Error Result:	Average value
Rho Result:	Average value

5. Change the MU887000A and SG frequencies according to Table 6.3.1-1"Measurement Point and Frequency" and repeat steps 2 to 4 over.
6. Change the SG output level and the MU887000A input level to –30 dBm and measure by repeating steps 2 to 5 over. (This output level reflects the calibration value for item 6.3.2.)
7. Change the Connect port setting for the connection with the MU887000A to Test Port2/3/4, successively and repeat steps 2 to 6 over.

6.3.8 About evaluation signals

The evaluation signals described in the performance test items 6.3.2 and 6.3.7 are set as follows. When the user is executing performance tests, set the SG actually used based on the following setting contents.

Install the MG3700A-002 Mechanical Attenuator option in the MG3700A. In addition, the MG3700A-011 High Frequency 6 GHz option is required to support Opt-015/016.

6.3.9 Sample format for test result sheets

Appendix A Specifications

This appendix lists the specifications of the MX887015A CDMA2000 Reverse Link TX Measurement software. Refer to Section 1.3 "Composition" for details of the product configuration.

These specifications assume use of the system at a constant temperature after warming-up the instruments for 30 minutes. The abbreviation (typ.) indicates the reference data at 20 to 30°C and is not a guaranteed value.
